ABSTRACT

The use of a measure of geographic proximity to help explain enrollment competition among postsecondary institutions was investigated. The measure, the number of miles between institutions, was obtained by determining the longitude and latitude coordinates for about 99% of the schools in the Higher Education General Information System universe. Differences in the average distance between a focal institution and its competitors were examined based on variations in institutional characteristics (e.g., control, enrollment size, selectivity, type, program emphasis, and region). The names of competing institutions were obtained from responses to a previous study of colleges and universities. Findings support the view that enrollment competition is primarily a local affair and that enrollment markets are highly segmented geographically. Private institutions had the greatest average distance followed by religious institutions. Additional findings concerning distance and the variables of control, size, selectivity, program emphasis, and region are presented and tabulated. A 74-page alphabetical list of higher education institutions by state provides the following information for each school: FICE code, county, and latitude and longitude coordinates. (SW)

GEOGRAPHIC PROXIMITY AND ENROLLMENT COMPETITION

Enrollment competition is becoming a more common dynamic among colleges and universities as the pool of traditional students decreases nationwide and students' interests in fields of study continue to shift. Our understanding of enrollment competition has increased in recent years with the appearance of a number of reports, books, and articles on the topic (e.g., Zemsky, Shaman, & Berberich, 1980; Rowse & Wing, 1982; Zemsky & Oedel, 1983; Zammuto, 1985). Most studies of enrollment competition have been based on the market segmentation model. According to the model, a market can be defined as consisting of distinct segments that are defined geographically and by the types of service provided for different consumers. Each segment is served by a similar set of institutions that compete for enrollments, but little competition occurs across market segments.

These studies show that higher education enrollment markets are highly segmented by institutional characteristics and by geographical proximity. With respect to institutional characteristics, competition generally occurs between similar schools. For example, public institutions usually compete with other public institutions, not private schools. Highly selective institutions tend to compete with other highly selective institutions, liberal arts institutions compete with other liberal arts institutions, and so on.

Zammuto (1985) suggests that these different types of relatively homogeneous competing networks of institutions are woven into a larger higher education market place through "linking" institutions, those that span boundaries between different types of institutions. For example, Zemsky and Oedel (1983) showed that institutions with religious affiliations competed with both public and independent institutions, indirectly linking those types of schools into larger networks. Zammuto (1985) also showed that moderately selective institutions indirectly linked high and low selectivity schools together into larger networks. Similarly, institutions with comprehensive programs serve to indirectly link liberal arts schools to institutions with professional program emphases.

But not all similar institutions in higher education compete for enrollments. Geographic proximity plays a major role in determining which like institutions will compete, and which other schools will be involved in indirect competition for enrollments. Zemsky and Oedel (1983) have indicated that the enrollment market place is segmented into local, state, regional and national markets. Local markets involve relatively few institutions in intense competition with each other, and competition at this level is the least homogeneous with respect to institutional characteristics. It is at this level that linking institutions probably play their most important role. At the other three levels, sets of competing institutions are more homogeneous but limited to schools within their geographic area.

As can be seen in the above summary, geographic proximity plays a major role in determining who competes with whom for enrollments. But a major problem with existing studies on enrollment competition is the gross nature of measures of institutional proximity. State or region designations are the most commonly used measures. And such measures have been shown to be significantly related to enrollment competition. For example, Zammuto's (1985) study showed that focal institutions identified competitors within their geographic region 87.6 percent of the time, and within the same state 73.5 percent of the time.

But gross measures of geographic competition have impeded more sophisticated research on enrollment competition for a number of reasons. First, the categorical nature of such variables makes it impossible to use them in multivariate analyses that could explore the dynamics of enrollment competition. This problem could be overcome by developing a continuous variable to represent geographic proximity. Second, state and region classifications are very imprecise. For example, an institution that is on the border of one state would be likely to compete with other institutions that are nearby, even if those institutions are in an adjacent city across the state border. But this type of institution would be treated the same as an institution in the middle of the state, whose competitors are elsewhere in the state. This problem could be corrected by developing a measure of geographic proximity that is insensitive to political boundaries and subdivisions.

The purpose of this study is to report on the development of a measure of geographic proximity that is both continuous in nature and ignores political boundaries and subdivisions, and to present bivariate distributions of this variable with other institutional characteristics. The solution to this problem is simple: the best measure of geographic proximity that is both continuous and ignores political boundaries is the number of miles between institutions. But, as will be shown in the next section, there are significant barriers that have to be overcome in order to create such a simple measure of distance.

Creating a Mileage Measure

Developing a mileage measure that could be used by higher education researchers is a nontrivial task. It is easy to measure the distance between any two institutions using a ruler and an atlas. But keep in mind that there are over 3,000 institutions in the HEGIS universe. To be broadly applicable, the measure would have to lend itself to the calculation of the distance between any two institutions within the HEGIS universe. To construct a complete index of distances between institutions would require approximately 4.5 million calculations, well beyond the ability of a horde of research assistants in any reasonable amount of time.

The simplest solution is to use the latitude and longitude coordinates of the city in which each college and university is located to calculate the distance between schools. The length of a degree of latitude on the earth's surface is approximately 69 miles. The length of a degree of longitude is another matter because they gradually converge toward the poles. One degree of longitude equals 69.17 miles at the equator, but as you move toward the poles, the distance between longitude lines diminishes. At 40^0 latitude, a degree of longitude equals 53 miles, at 60° the length of a degree of longitude is about 35 miles, and at 90° where all lines meet, it is zero miles. Mathematically, the relationship between latitude and the length of a degree of longitude is expressed as:

$$1^{\circ} \text{ longitude} = 1^{\circ} \text{ latitude} \times \text{cosine latitude}$$

Using this information, calculating the distance between two points becomes relatively easy, distance being the hypotenuse of a right triangle. The following calculations are involved:

$$a = (\text{latitude}_f - \text{latitude}_c) \times 69.055$$

$$b = \text{longitude}_f - \text{longitude}_c \times (69.055 \times \text{cosine latitude}_f)$$

$$d = \sqrt{a^2 + b^2}$$

Where:

f = focal institution
c = competing institution
d = distance

These calculations do not correct for the curvature of the earth's surface but, as will be shown in the following sections, the average distance between institutions is so small that the error is insignificant.

While calculating the distance between two coordinates is a relatively simple computational task, assembling the listing of coordinates for the HEGIS universe was more problematic. First, a data tape was obtained from the National Center for Atmospheric Research (NCAR) that contained a listing of all weather reporting stations in the United States. Because of the historical nature of the tape, it was possible for a city to have more than one set of coordinates due to movement of weather reporting facilities over time. Thus the first step was to reduce, by hand, the number of entries for any city to one. Once this was accomplished, it was possible to match cities in the HEGIS universe with cities on the NCAR data tape. This procedure yielded a match for about 2,000, or two-thirds, of the institutions. Coordinates were obtained for approximately two-thirds of the remaining institutions from the index of the National Atlas (U.S. Geological Survey, 1970). Coordinates for the remaining three hundred or so institutions were estimated using maps.

The resulting data file contains the longitude and latitude coordinates for approximately 99 percent of the HEGIS universe. A hard copy listing is attached as the appendix. (To assist other researchers, a data tape with documentation is available from the Organizational Studies Division for the cost of the tape.) The listing is organized alphabetically by state, and then by institution. All latitude coordinates are "north," while all longitude coordinates are "west". Thus the coordinates for a school in Denver would be 39° N and 104° W. Given that the coordinates, in most instances, are for the weather observation facility in the city in which an institution is located, distances calculated between any two institutions should be treated as approximate. On the average such errors should be randomly distributed through the population, meaning that the average distances for the population should be reasonably unbiased approximations.

Distance and Other Institutional Characteristics

We can begin to gain a better understanding of the role of geographic proximity in enrollment competition by examining differences in the average distance between a focal institution and its competitors based on variations in institutional characteristics (e.g., control, enrollment size, selectivity, type, program emphasis, and region). Data identifying competing institutions were collected during a 1983 Organizational Studies Division field study of the management and performance of four-year institutions. As part of that study, a supplemental questionnaire was sent to institutional research officers at 334 participating institutions. The supplemental questionnaire asked these individuals to identify up to eight competing institutions. Usable responses were returned by institutional research officers for 269 institutions. A total of 1,269 competing institutions were mentioned for an average of 4.8 competitors identified by each focal institution.[1] For the following analyses, 12 of those institutions were eliminated from the data set. Ten of these institutions listed no competitors, the other two institutions were located in Alaska and Hawaii. It was felt that including these institutions would skew the results.

---

[1] The variables used in these distributions are defined in the same manner as those in Zammuto (1985). More extensive variable definitions can be found there.

1. Average distance. Table 1 presents the percentile distribution of institutions by the average distance between a focal institution and its competitors. The results show that the average distance between a focal school and its competitors was less than 85 miles for the majority of the sample. Only five percent of the sample clearly fell into a national market segment, where the average distance of a school's competitors was more than 520 miles. This finding supports the contention in the literature that enrollment competition is primarily a local affair and that enrollment markets are highly segmented geographically.

2. Institutional type. Table 2 provides information on the average distance between competing institutions by type of the focal institution. Type was defined using the NCHEMS institutional classification system (Makowski & Wulfsberg, 1981). As was noted in Zammuto (1985), institutions tended to nominate identify competitors at the same or a higher level in the institutional hierarchy. For example, general baccalaureate institutions usually identified other general baccalaureate institutions as competitors. They also tended to identify comprehensive and major doctoral institutions as competitors. Rarely did an institution identify institutions lower in the institutional hierarchy. For example, comprehensive institutions usually identified other comprehensive and major doctoral

institutions as competitors, but rarely identified general baccalaureate institutions. The anomaly was specialty institutions, which identified major doctoral and other specialty institutions as being their primary competitors.

The results shown in Table 2 generally fit the overall pattern of these results. Average distance between focal and competing schools is higher for major doctoral and specialty institution than it is for comprehensive and general baccalaureate institutions. Surprisingly,, the average distance between competitors for general baccalaureate and comprehensive institutions is virtually the same, while comprehensive schools are generally considered higher in the institutional hierarchy.

3. Enrollment size. Table 3 presents the average mileage between competitors by institutional enrollment size. Zammuto (1985) reported that the majority of focal institutions saw themselves as competing with large institutions regardless of their own size. Table 3 indicates that while all focal institutions may see large institutions as their major source of competition, the average distance between the focal and competing schools increases as the size of the focal school decreases. In essence, the smaller the school the larger the radius of its enrollment market.

4. Institutional control. Table 4 shows the average distance between focal and competing schools based on institutional control. The general expectation was that private institutions recruit students from a larger geographic region than public institutions. Therefore, their average distance scores

should be higher than those for public institutions. Table 4 indicates that this is the case. Independent institutions have the greatest average distance followed by religious institutions. Public institutions had the smallest average distance, which was not greatly dissimilar from that for religious institutions.

The difference between independent and religious institutions may partially be explained by a finding in Zammuto (1985). It was reported there that the majority of competitors identified by public institutions were other public institutions, and the majority of competitors identified by independent institutions were other independent institutions. In contrast, religiously affiliated institutions tended to identify public and independent institutions as well as other religious institutions as competitors, suggesting that they served a linking function in enrollment markets. This result may indicate that religious institutions compete locally with public institutions and with private institutions at a greater distance.

5. Institutional selectivity. Table 5 presents the average mileage between focal and competing institutions by institutional selectivity. As would be expected, the results show that the average distance between a focal school and its competitors increases as selectivity increases. But the difference between low and medium selectivity schools is marginal while that between them and high selectivity schools is substantial.

6. Program emphasis. Table 6 shows the average mileage between focal and competing schools by institutional program emphasis. The results indicate that the average distance between

focal and competing schools is somewhat greater for institutions with liberal arts and comprehensive programs as compared to institutions with professional programs. Interestingly, the scores for liberal arts schools, which had the greatest average distance also had the smallest standard deviation, suggest that they are more consistent in the breadth of their recruiting areas as compared to institutions with comprehensive and professional programs as a group.

7. Geographic region. While the sample was not selected to be balanced geographically, an examination of average distances by region provides some useful information. As is shown in Table 7, the average mileage between focal and competing schools increases with movement westward. The middle east, New England, and southeast regions were found to have the lowest average distance scores, while the Great Lakes and plains regions ranked in the middle. Western regions had the highest average mileage scores, with the exception of the Rocky Mountain region. (Given the small number of institutions (n=6) included for the Rocky Mountain region, the low average mileage score may be an aberration.)

Overall, this finding can be interpreted as reflecting differences in population densities, which decrease with movement west. As the density of the population in an area decreases, the number of institutions of higher education also decreases. Therefore, competitors in more sparsely populated states are likely to be more distant than similar schools along the eastern seaboard.

Summary

Overall, the distribution of average distances between focal and competing institutions by selected institutional characteristics is consistent with the literature to date on enrollment competition. But these distributions also indicate that the structuring of enrollment markets by institutional characteristics may not be as clear cut as previously thought. For example, segmentation by institutional type, control, and selectivity appears to be less rigid than previously thought. For example, there is not a simple progression in distance by selectivity. Low and moderately selective institutions appear to compete in the same sized enrollment markets, while highly selective institutions compete over a much larger geographic area.

While this study has not provided any definitive answers to questions concerning the structure of enrollment competition, the measure of distance developed does open up new research opportunities. It is now possible to use the concept of geographic proximity in a more sophisticated manner, and to explore a variety of issues concerning competition that have been inaccessible, in the past.
